1. INTRODUCTION

Anahem d.o.o. Laboratory (hereinafter referred to as Anahem) from Belgrade (Serbia) was appointed by Asociation ZA Drinking Fountains, Zaječar, to carry out the sampling and laboratory analyses of water, sediments and ichthyofauna in the rivers of the Crni Timok, the Veliki Timok, the Borska reka, the Pek, the Dunav at the confluence of the Timok within the Project "ENVIRONMENTAL RESPONSE TO MINING EXPANSION IN TIMOČKA KRAJINA".

The purpose of the study is to investigate existing situation and further monitoring of harmful effects of mining and urban development on the environment in Timočka Krajina. In order to estimate existing situation, based on the previous campaign carried out from 31.08.2022 to 03.09.2022. samples were taken at the ten locations described in the next chapter. Figure 1 shows the map of the area - Timočka Krajina.

Figure 1. Map of Timočka Krajina

Sampling was carried out in the period from 05.12.2022 to 11.12.2022. Sample analysis was done in accordance with the scope defined by offer 12051609, which included:

The analysis of the samples was done in accordance with the scope defined by the offer 12051609, which included:

- Physico-chemical analyzes: 1) Water: color, odor, temperature, electrical conductivity, pH, concentration of dissolved oxygen, as well as concentration of SO_4^{2-} , Cl^- , PO_4^{3-} , NO_3^- , NH_3 , As, Cd, Cu, Fe, Mn, Ni, Pb, Hg, Zn, Co, Sr, S, Ca, Mg, K, Na and

Cr; organic and microbiological pollution. 2) Sediment: color and concentration of Mn, Ni, Co, Sr, As, Cd, Cr, Hg, Cu, Pb and Zn; radioactivity. 3) Ichthio fauna samples: radioactivity and Cd, Pb, As, Cu, Hg, Cr, Co, Ni, Mn, Zn, Fe and Hg concentration.

2. LOCATIONS OF SAMPLING POINTS

2.1. River Pek

In order to determine the quality of the river Pek, as well as the impact of mining in Majdanpek, which together with flotation and landfills is a potential source of pollution, sampling was carried out on the rivers shown in Figure 2. Figure 3 shows a satellite view of the sampling points, and Table 1 shows the GPS coordinates. and sample labels.

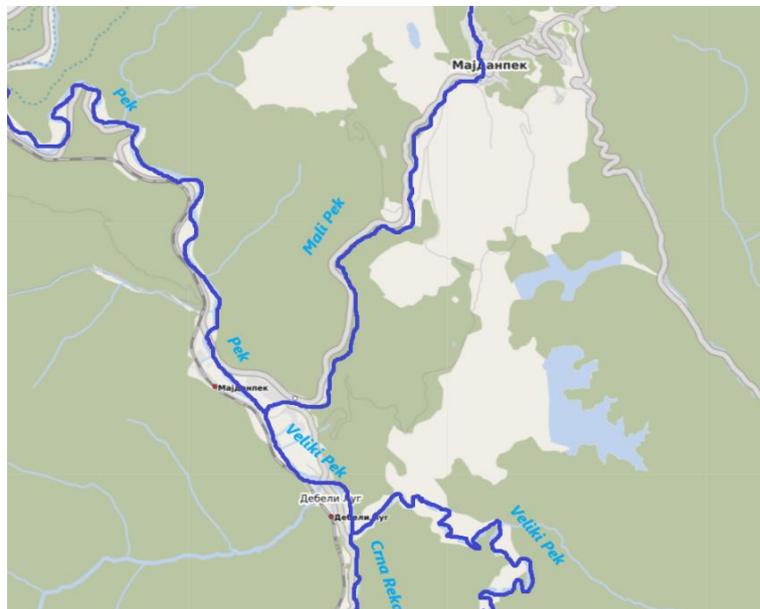

Figure 2. Representation of the rivers on which the sampling was carried out

2.2. Borska reka, Brestovačka reka, Kriveljska Reka, Bela Reka, Timok

Upstream from Bor, the Borska reka is directed into the Kriveljska Reka through a tunnel, in order to open an open-pit copper mine in its valley. Downstream from Bor, municipal waste water, untreated mine water and waste water from metallurgy and basic chemistry plants are discharged into the bed of the former watercourse. A large amount of flotation tailings flows into the river, flooding the banks of this river and Veliki Timok downstream from its mouth. It flows through the villages of Slatina and Vražognac. The analysis of the samples taken from the rivers shown in Figure 4 was carried out in order to determine the pollution of the Timok River based on the analysis of samples from the rivers that flow into it.

Water and sediment samples of the Crni Timok River were taken in order to determine the impact of mining and the release of toxic substances on water quality, as well as on ichthyofauna. This is particularly significant because of the Timok trout, an autochthonous species, which is particularly threatened by the discharge of wastewater from the Čukaru Peki mine. Also, samples of the Brestovačka Reka, Kriveljska Reka and Bela Reka were taken at representative locations in order to determine potential pollution.

3. TECHNIQUES AND METHODS

3.1. Sampling and analysis of water

Sampling and laboratory analysis of surface and groundwater was performed according to standard and validated accredited methods. The following methods for sampling were used: SRPS EN ISO 5667-1, SRPS EN ISO 5667-3, SRPS EN ISO 5667-4, SRPS EN ISO 5667-6, and SRPS EN ISO 19458. The field analytes were tested at the site. A portable fridge was used to keep samples cold during their transport to the laboratory. Laboratory analyses of water samples were made by using methods given in Table 5.

Table 5. List of methods used for the surface water analysis.

Parameter	METHOD
FIELD MEASUREMENTS	
Water temperature	EPA 170.1
pH Value	EPA 150.1
Conductivity	EPA 120.1
Dissolved Oxygen (O ₂)	EPA 360.1
LABORATORY MEASUREMENTS	
Color	SRPS EN ISO 7887
Odor	DML 2.7
Sulfates (SO ₄ ²⁻), Chloride (Cl ⁻), Orthophosphates, Nitrate (NO ₃ ⁻), Nitrite (NO ₂ ⁻)	ISO 10304-1
Ammonium ion (NH ₄ -N)	SRPS ISO 7150-1
Cadmium (Cd), Nickel (Ni), Lead (Pb), Zinc (Zn), Cobalt (Co)	EPA 200.8
Arsenic (As), Copper (Cu), Chromium (Cr) Total, Iron (Fe), Manganese (Mn), Strontium (Sr), Sulphur	SRPS EN ISO 11885
Magnesium, Potassium, Calcium, Sodium	ISO 14911
Phenols	SRPS ISO 6439
Petroleum hydrocarbons (C10-C40)	ISO 9377-2
Surface active agents (such as lauryl sulfate)	SM 5540C
AOX	DML 2.2
MICROBIOLOGY MEASUREMENTS	
Fecal coliform count in 100 ml MPN Colilert	DML 2.9
Total coliform count in 100 ml MPN Colilert	DML 2.9
Intestinal enterococci	DML 2.10
Aerobic heterotrophic bacteria	SRPS EN ISO 62220

3.2. Sampling and analysis of sediment

Accredited methods were used for sediment sampling and analysis. The sediment sampling procedure was performed according to the SRPS ISO 5667-12 method. Laboratory analyzes of sediment samples were performed using the methods given in Table 6.

Table 6. List of methods used for sediment analysis.

Parameter	METHOD
Metals: Arsenic (As), Cadmium (Cd), Chromium (Cr), Copper (Cu), Lead (Pb), Nickel (Ni), Zinc (Zn), Manganese (Mn), Cobalt (Co), Strontium (Sr)	EPA 3051A/EPA 6010c
Clay content	ISO 11277
Content of organic matter	EN EN TC WI
Content of radionuclides	SRPS EN ISO 18589-3

3.3. Analysis of fish samples

Table 7 shows the methods used for the analysis of fish samples.

Table 7. List of methods used for the analysis of fish samples.

Parameter	METHOD
Cobalt (Co), Nickel (Ni), Manganese (Mn), Chromium (total)	DML 1.1
Cadmium (Cd), Lead (Pb), Arsenic (As), Mercury (Hg), Copper (Cu), Iron (Fe), Zinc (Zn)	SRPS EN 15763
Content of radionuclides	IAEA TRS 295

4. EXPERIMENTAL RESULTS

4.1. Limit values of pollutants in surface waters and criteria for assessing the quality of sediment and permitted methods of handling washed sediment.

Table 8. Regulated limit values of parameters for surface water
(Official Gazette RS, No 50/2012)..

Parameter	Limit values ¹				
	I class	II class	III class	IV class	V class

According to the Regulation on the categorization of watercourses ("Official Gazette of the RS", No. 5/68), the Pek River belongs to Class III from its source to its confluence with the Danube. Crni Timok from the source to Zaječar and from Zaječar to the confluence the Borska river belongs to the II.

The criteria for assessing the quality of the sediment and the permitted ways of dealing with washed sediment (Official Gazette RS, No 50/2012) are shown in table 9.

Table 9. The criteria for assessing the quality of the sediment and the permitted ways of dealing with washed sediment

Class	Criteria	Ways of handling washed sediment
0	≤ Target value	The concentrations of pollutants in the sediment are at the level of the natural background. Sediments can be dislodged without special protection measures.
1	> Target value and ≤ Limit value	The sediment is slightly polluted. During dislocation, disposal is permitted without special protection measures in a zone up to 20 m wide in the vicinity of watercourses.
2	> Limit value and ≤ Verification limit	
3	> Verification level ≤ Remediation value	The sediment is polluted. It is not allowed to dispose of it without special protective measures. It is necessary to store it in controlled conditions with special protection measures in order to prevent the spread of polluting substances in the environment.
s4	> Remediation value	Extremely polluted sediments. Remediation or storage of ground material in controlled conditions with special protection measures is mandatory to prevent the spread of pollutants into the environment.

4.2. Analysis of water and sediment

4.2.1. Analysis results - water and sediment quality – Majdanpek area

The results of the analysis of water samples - Majdanpek area are shown in table 10.1 and 10.2

MDK- Rulebook on maximum concentrations of certain contaminants in food, Official Gazette of the RS no. 81/2019, 126/2020, 90/2021 and 118/2021, Annex 1.

* Rulebook on the limits of radionuclide content in drinking water, foodstuffs, animal feed, medicines, items of general use, construction materials and other goods put into circulation ("Official Gazette of RS", No. 36/2018).

5. CONCLUSION

Based on the results of laboratory tests, in order to determine the impact of mining on the quality of the rivers - Crni Timok, Veliki Timok, Borska reka, Pek and Dunav in accordance with the Regulation on limit values of pollutants in surface and underground waters and sediment and deadlines for their achievement (" Official Gazette of the RS", no. 50/12) and the Decree on the categorization of watercourses ("Official Gazette of the RS", no. 5/68), it can be concluded that there is pollution in the investigated rivers of Timočka Krajina.

The Pek river is formed by the confluence of two rivers - Veliki Pek and Mali Pek. In order to determine the potential pollution of the mentioned river, samples were taken at the points of interest - Mali Pek before the area of potential pollution, Mali Pek before the sewage inlet, Mali Pek before and after open-pit mine in Majdanpek, Veliki Pek before the area of potential pollution (near the village of Leskovo), Crna Reka, Veliki Pek after the confluence of the Crna Reka, Veliki Pek downstream from the tailings pond in Valja Fundata and finally at the target location - after the mouth of both rivers and the formation of the Pek River, as well as on its further course. By examining the mentioned samples, it can be concluded that:

No contamination was detected in the Mali Pek river sample before the sewage inlet. Further along the river, i.e. Increased retention of ammonium ions, orthophosphate, iron, manganese and sulfate was detected in the water sample after open-pit mine. Microbiological analysis showed contamination with aerobic mesophilic bacteria. Also, the concentration of copper in the sample after surface mining increases and this parameter should be monitored. As for the Veliki Pek River, the values obtained for the analyzed parameters are largely in line with the better quality classes in the part of the stream near the village of Leskovo. However, the quality of the river gradually deteriorates in the further course.

Finally, the analysis showed that in accordance with the above-mentioned Regulations, there is a certain contamination that violates the class of the Pek River, which according to the Regulation falls into Class III. In particular, an increased concentration of sulfate, orthophosphate, iron, manganese and aerobic heterotrophic bacteria was detected.

As for the examination of sediment samples at the mentioned locations, the analysis showed that in the course of the river before the Majdanpek area, no pollution was detected. Before the sewage inflow, concentrations of copper and nickel were detected, which after the inflow exceeded the remediation values. A lower concentration of zinc and cadmium also appears after the inflow of sewage. In its further course, the Mali Pek river passes through the mine, after which concentrations of copper, arsenic, zinc and nickel exceeding the remediation values were detected. Analysis of samples from the Pek River after the confluence of the Mali and Veliki Pek rivers showed contamination of arsenic, copper and zinc with values above remediation, lead concentration above the limit value and nickel above the verification level.

In the further course, i.e. in the sediment sample after the surface mining was detected significant. The assessment of sediment quality is, in accordance with the mentioned Regulation, that the sediment is polluted. The content of the analyzed metals is much higher in the sediment samples than in the water samples, which is a consequence of the continuous flow of water and the fact that a few days before the sampling, it rained heavily.

Analysis of a sample of surface water from the Brestovačka river taken outside the area of potential pollution did not indicate contamination. The results of the analysis of water samples of the Brestovačka River after the inflow of the waste channel from the Čukaru Peki mine show that certain values are slightly increased in relation to the values of the parameters at the location before the inflow, which is related to the heavy rainfall in the days before sampling. The analysis of the Crni Timok river water sample after the Brestovačka river inlet did not show a significant increase in the concentrations of the analyzed parameters. The analysis of sediment samples showed that an increased concentration of copper - above the remediation value - was detected in the sample at the location of the waste channel from the Čukaru Peki mine. There is also a concentration of nickel above the verification level in the tailings sample.

The further course of the Crni Timok is categorized as class II and for the most part corresponds to the same, up to the mouth of the Bor river. The surface water of the Borska reka, from Bor to its confluence with Crni Timok, is categorized as a river of poor quality and belongs to quality class IV. Immediately after the mine near Bor, concentrations of copper, arsenic and nickel above the remediation value were detected in sediment samples. Analysis of the samples showed an increased concentration of sulfate. The color of the samples of this water is brown-yellow. Based on the examination of water samples taken before and after the confluence of the Bor River into Veliki Timok, it can be concluded that the confluence of the Borska reka leads to an increase in the concentration of certain metals in both water and sediment. The biggest detected changes in the water samples are in the concentration of copper, iron and manganese. The further course of the Timok river moves in the direction of the Dunav. Concentrations of metals such as copper, arsenic, cadmium, nickel and zinc were also detected in this part of the river. In chapter 4, the concentrations of the analyzed parameters are given for all investigated locations, as well as the limit values in accordance with the Regulation. The content of the mentioned metals is not negligible and it is necessary to monitor the quality of the water and sediment of the Timok River as well as its tributaries in order to monitor the quality.

6. APPENDIX - Pictures from the field
